1 | Introduction

Given the opportunity to review the design document and related smart contract source code of the MaxFun protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About MaxFun

MaxFun is an innovative decentralized platform designed to enable the seamless creation and management of automated market maker AMM pairs, leveraging a robust and scale token ecosystem. It is built to provide a user-friendly environment for launching tokens, initializing liquidity pools, conducting secure token trades, and migrating token pairs to prominent decentralized exchanges such as UniswapV2. The basic information of audited contracts is as follows:

1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (<https://t.me/peckshield>), Twitter (<http://twitter.com/peckshield>), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact	High	Critical	High	Medium
	Medium	High	Medium	Low
	Low	Medium	Low	Low
		High	Medium	Low
		Likelihood		

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [8]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact, and can be accordingly classified into four categories, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further

	Following Other Best Practices

deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the `MaxFun` implementations. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	2	
Low	1	
Informational	0	
Total	3	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in [Section 3](#).

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 medium-severity vulnerabilities and 1 low-severity vulnerabilities.

Table 2.1: Key Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Improved Validation of Function Arguments	Coding Practices	Resolved
PVE-002	Medium	Potential Denial-of-Service in Token Graduation	Business Logic	Resolved
PVE-003	Medium	Trust Issue of Admin Keys	Security Features	Mitigated

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Improved Validation of Function Arguments

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: MaxFunFactory
- Category: Coding Practices [5]
- CWE subcategory: CWE-1126 [1]

Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The `MaxFun` protocol is no exception. Specifically, if we examine the `MaxFunFactory` contract, it has defined a number of protocol-wide risk parameters, such as `buyFee` and `sellFee`. In the following, we show the corresponding routines that allow for their changes.

```

97     function setFeeParameters(
98         address newVault_,
99         uint256 buyFee_,
100        uint256 sellFee_
101    ) public onlyRole(ADMIN_ROLE) {
102        require(newVault_ != address(0), "MaxFunFactory: Zero addresses are not allowed.");
103
104        taxVault = newVault_;
105        buyFee = buyFee_;
106        sellFee = sellFee_;
107
108        emit FeeParametersSet(newVault_, buyFee_, sellFee_);
109    }
110    ...
111    function setLaunchFee(uint256 newLaunchFee) external onlyRole(ADMIN_ROLE) {
112        launchFee = newLaunchFee;
113
114        emit LaunchFeeSet(newLaunchFee);
115    }
116    ...

```

```

117     function setGradFee(uint256 newGradFee) external onlyRole(ADMIN_ROLE) {
118         gradFee = newGradFee;
119
120         emit GradFeeSet(newGradFee);
121     }
122     ...
123     function setInitialSupply(uint256 newSupply) external onlyRole(ADMIN_ROLE) {
124         initialSupply = newSupply;
125
126         emit InitialSupplySet(newSupply);
127     }
128     ...
129     function setLaunchPointPercentage(uint256 newLaunchPointPercentage) external
130         onlyRole(ADMIN_ROLE) {
131         launchPointPercentage = newLaunchPointPercentage;
132
133         emit LaunchPointPercentageSet(newLaunchPointPercentage);
134     }

```

Listing 3.1: Example Setters in MaxFunFactory

These parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. Based on the current implementation, certain corner cases may lead to an undesirable consequence. For example, an unlikely mis-configuration of `newLaunchPointPercentage` may fail any token graduation attempt, hence bringing inconvenience to the adoption of the protocol.

Recommendation Validate any changes regarding these system-wide parameters to ensure they fall in an appropriate range.

Status This issue has been resolved in the following commit: [4f8bda5](#).

3.2 Potential Denial-of-Service in Token Graduation

- ID: PVE-003
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: MaxFunManager
- Category: Business Logic [6]
- CWE subcategory: CWE-841 [3]

Description

As mentioned earlier, MaxFun builds an innovative DeFi platform that caters to the launch, liquidity management, and automated market operations of new tokens. When a new token is launched, it

will go through the so-called graduation process. Our analysis shows the token graduation may suffer from a denial-of-service issue.

In the following, we show the implementation of the related `launchOnUniswap()` routine. When the new token launch process reaches the target `launchPointShare`, this routine will be invoked. As part of its logic, it will call the `swapFactory` contract to create the token pair and add the initial liquidity. However, the token pair creation may be blocked (line 162) if the external pair is already created, resulting in the token graduation failure.

```

132     function launchOnUniswap(address tokenAddress, address asset) public onlyFactory
133         returns (address) {
134             address pairAddress = IMaxFunCurve(maxFunCurve).getPair(tokenAddress, asset);
135
136             IMaxFunPair pair = IMaxFunPair(pairAddress);
137
138             uint256 assetBalance = pair.assetBalance();
139
140             IMaxFunCurve(maxFunCurve).triggerGraduation(tokenAddress, asset);
141
142             address uniswapV2Pair = _createUniswapV2Pool(tokenAddress, asset);
143
144             uint256 txFee = (maxFunFactory.getGradFee() * assetBalance) / maxFunFactory.
145                 getPercentageDecimals();
146
147             IERC20(asset).safeTransfer(maxFunFactory.getTaxVault(), txFee);
148
149             _addInitialLiquidity(tokenAddress, asset);
150
151             emit Graduated(tokenAddress, uniswapV2Pair);
152
153             return uniswapV2Pair;
154     }

```

Listing 3.2: `MaxFunManager::launchOnUniswap()`

```

161     function _createUniswapV2Pool(address tokenAddress, address asset) internal returns
162         (address uniswapV2Pair_) {
163         uniswapV2Pair_ = IUniswapV2Factory(swapFactory).createPair(tokenAddress, asset);
164
165         _liquidityPools.add(uniswapV2Pair_);
166         emit UniswapV2PairCreated(uniswapV2Pair_);
167
168         return uniswapV2Pair_;
169     }

```

Listing 3.3: `MaxFunManager::_createUniswapV2Pool()`

Recommendation Revise the above routine to ensure the token graduation is not blocked.

Status This issue has been resolved in the following commit: `2a64d32`.

3.3 Trust Issue of Admin Keys

- ID: PVE-003
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: Multiple Contracts
- Category: Security Features [4]
- CWE subcategory: CWE-287 [2]

Description

In the audited protocol, there is a privileged `owner` account. This account plays a critical role in governing and regulating the system-wide operations (e.g., configure parameters, manage contracts, execute privileged operations, upgrade contracts, etc.). Our analysis shows that this privileged account needs to be scrutinized. In the following, we use the `MaxFunManager` contract as an example and show the representative functions potentially affected by the privileged account.

```

69     function setMaxFunFactory(address newFactory) external onlyOwner {
70         maxFunFactory = IMaxFunFactory(newFactory);
71
72         emit MaxFunFactorySet(newFactory);
73     }
74
75     function setSwapRouter(address newRouter) external onlyOwner {
76         swapRouter = newRouter;
77
78         emit SwapRouterSet(newRouter);
79     }
80
81     function setSwapFactory(address newFactory) external onlyOwner {
82         swapFactory = newFactory;
83
84         emit SwapFactorySet(newFactory);
85     }
86
87     function setMaxFunCurve(address newMaxFunCurve) external onlyOwner {
88         maxFunCurve = newMaxFunCurve;
89
90         emit MaxFunCurveSet(newMaxFunCurve);
91     }

```

Listing 3.4: Privileged Operations in `MaxFunManager`

We understand the need of the privileged functions for proper protocol operations, but at the same time the extra power to the privileged admin may also be a counter-party risk to the protocol users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among protocol users.

In the meantime, a number of protocol contracts make use of the proxy contract to allow for future upgrades. The upgrade is a privileged operation and the management of the related admin key also falls in this trust issue.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated as the team plans to assign admin role to a multi-sig wallet.

4 | Conclusion

In this audit, we have analyzed the design and implementation of the `MaxFun` protocol, which is an innovative decentralized platform designed to enable the seamless creation and management of automated market maker `AMM` pairs, leveraging a robust and scale token ecosystem. It is built to provide a user-friendly environment for launching tokens, initializing liquidity pools, conducting secure token trades, and migrating token pairs to prominent decentralized exchanges such as `UniswapV2`. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
