1 | Introduction

Given the opportunity to review the design document and related smart contract source code of the ZKEX Vesting support, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts is well designed and engineered, though it can be further improved by addressing our suggestions. This document outlines our audit results.

1.1 About ZKEX Vesting

ZKEX is an omni-chain DEX for a multi-chain world, secured with zero-knowledge proofs. It provides services, including Trade Spot and Perpetual Contracts without limits. This audit covers the token vesting support used in the ZKEX ecosystem. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of ZKEX Vesting

Item	Description
Name	ZKEX
Type	EVM Smart Contract
Platform	Solidity
Audit Method	Whitebox

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (<https://t.me/peckshield>), Twitter (<http://twitter.com/peckshield>), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact	High	Medium	Low
	Critical	High	Medium
	High	Medium	Low
	Medium	Low	Low
Likelihood			

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [6]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy

Table 1.3: The Full Audit Checklist

Category	Checklist Items
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy

	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the vesting support in `ZKEX`. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	
Low	1	
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in [Section 3](#).

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 low-severity vulnerability.

Table 2.1: Key ZKEX Vesting Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Improved Validation of Function Arguments	Coding Practices	Resolved
PVE-002	Medium	Trust on Admin Keys	Security Features	Resolved

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Improved Validation of Function Arguments

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: TokenVesting
- Category: Coding Practices [4]
- CWE subcategory: CWE-1126 [1]

Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The `TokenVesting` contract is no exception. Specifically, if we examine the audited contract, it has defined a number of risk parameters for each vesting schedule, such as `tgeAmount`, `cliffDuration`, `vestingInterval`, and `vestingRound`. In the following, we show the corresponding routine to create a new vesting schedule.

```
83     function createVestingSchedule(  
84         uint256 _scheduleId,  
85         address payable _beneficiary,  
86         uint256 _amountTotal,  
87         uint256 _tgeAmount,  
88         uint256 _cliffDuration,  
89         uint256 _cliffAmount,  
90         uint256 _vestingInterval,  
91         uint256 _vestingRound  
92     ) external onlyOwner {  
93         require(!vestingSchedules[_scheduleId].created, "TokenVesting: schedule created"  
94             );  
95         require(_beneficiary != address(0), "TokenVesting: beneficiary must be non-zero  
96             address");  
97         require(_amountTotal > 0, "TokenVesting: amount must be > 0");  
98         require(getRemainingAmount() >= _amountTotal, "TokenVesting: insufficient tokens  
99             ");  
100        require(tge >= 0, "TokenVesting: must set tge time");
```

```

98     require(_amountTotal >= _tgeAmount + _cliffAmount, "TokenVesting: cannot exceed
99         amount total");
100     if (_vestingInterval == 0) {
101         require(_amountTotal == _tgeAmount + _cliffAmount, "TokenVesting: cannot
102             remaining token");
103     } else {
104         require(_vestingRound != 0, "TokenVesting: vesting interval must non-zero");
105     }
106     vestingSchedules[_scheduleId] = VestingSchedule(
107         true,
108         _beneficiary,
109         _amountTotal,
110         _tgeAmount,
111         _cliffDuration,
112         _cliffAmount,
113         _vestingInterval,
114         _vestingRound,
115         0,
116         false
117     );
118     vestingSchedulesTotalAmount = vestingSchedulesTotalAmount + _amountTotal;
119 }

```

Listing 3.1: TokenVesting::createVestingSchedule()

These parameters define various aspects of the vesting schedules and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. For example, the above vesting schedule creation can be improved by enforcing `require(tge > 0)`, not current `require(tge >= 0)` (line 97).

Recommendation Validate any changes regarding these parameters to ensure a new vesting schedule is properly created.

Status The issue has been fixed by this commit: 2cfabd4.

3.2 Trust Issue of Admin Keys

- ID: PVE-00
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: TokenVesting
- Category: Security Features [3]
- CWE subcategory: CWE-287 [2]

Description

In the `TokenVesting` contract, there is a privileged `owner` account that plays a critical role in governing and regulating the vesting-wide operations (e.g., create/revoke a vesting schedule and update TGE). It also has the privilege to control or govern the flow of assets managed by this contract. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and the related privileged accesses in current contracts.

```

75     function updateTge(uint256 _tge) external onlyOwner {
76         require(_tge >= tge, "TokenVesting: cannot turn back TGE time");
77         tge = _tge;
78     }
79
80     /**
81      * @notice Creates a new vesting schedule for a beneficiary.
82      */
83     function createVestingSchedule(
84         uint256 _scheduleId,
85         address payable _beneficiary,
86         uint256 _amountTotal,
87         uint256 _tgeAmount,
88         uint256 _cliffDuration,
89         uint256 _cliffAmount,
90         uint256 _vestingInterval,
91         uint256 _vestingRound
92     ) external onlyOwner {...}
93
94     /**
95      * @notice Revokes the vesting schedule for given identifier.
96      * @param _scheduleId the vesting schedule identifier
97      */
98     function revoke(uint256 _scheduleId) external onlyOwner onlyNotRevoked(_scheduleId)
99         {...}

```

Listing 3.2: Example Privileged Functions in `TokenVesting`

Note that if the privileged `owner` account is a plain EOA account, this may be worrisome and pose counter-party risk to the exchange users. A multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key

concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been resolved as the team confirms it is part of the vesting design.

4 | Conclusion

In this audit, we have analyzed the design and implementation of the token vesting support in ZKEX, which is an omni-chain DEX for a multi-chain world, secured with zero-knowledge proofs. It provides services, including Trade Spot and Perpetual Contracts without limits. This audit covers the token vesting support used in the ZKEX ecosystem. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Moreover, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
