1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Xterio's FansCreate protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Xterio's FansCreate

Xterio is a Web3 gaming ecosystem & infrastructure, distinguishing itself as a gaming publisher with top-notch development skills and unparalleled distribution expertise. The audited FansCreate protocol is a social component of Xterio that aims to revolutionize the way people build their network. Everyone now has the power to invest in the success of their friends through the innovative use of ERC1155 to represent the share ownership. The basic information of the audited protocol is as follows:

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact \ **Likelihood**	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [6]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract

Table 1.3: The Full Audit Checklist

Category	Checklist Items
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function

is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `FansCreate` protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	■
Low	1	■
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 low-severity vulnerability.

Table 2.1: Key FansCreate Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Strengthened Validation of Function Parameters	Coding Practices	Resolved
PVE-002	Medium	Trust Issue of Admin Keys	Security Features	Mitigated

Besides the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Strengthened Validation on Function Arguments

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: FansCreateCore
- Category: Coding Practices [4]
- CWE subcategory: CWE-1126 [1]

Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The FansCreate protocol is no exception. Specifically, if we examine the FansCreateCore contract, it has defined a number of protocol-wide states and parameters, such as protocolFeeRatio, projectFeeRatio, and creatorFeeRatio. In the following, we show the corresponding routines that configure these parameters.

```
    function setFeeRatio(
        uint256 _protocolFeeRatio,
        uint256 _projectFeeRatio,
        uint256 _creatorFeeRatio
    ) external onlyRole(MANAGER_ROLE) {
        protocolFeeRatio = _protocolFeeRatio;
        projectFeeRatio = _projectFeeRatio;
        creatorFeeRatio = _creatorFeeRatio;
        emit SetFeeRatio(_protocolFeeRatio, _projectFeeRatio, _creatorFeeRatio);
    }

    function setProtocolFeeRecipient(
        address _protocolFeeRecipient
    ) external onlyRole(MANAGER_ROLE) {
        protocolFeeRecipient = _protocolFeeRecipient;
        emit SetProtocolFeeRecipient(_protocolFeeRecipient);
    }
```

Listing 3.1: FansCreateCore::setFeeRatio()/setProtocolFeeRecipient()

These states and parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. For example, the above routines can be improved by enforcing the following requirement: `require( _protocolFeeRatio + _projectFeeRatio + _creatorFeeRatio < FEE_RATIO_DENOMINATOR))`.

Recommendation Validate any changes regarding these system-wide parameters to ensure they fall in an appropriate range.

Status This issue has been fixed in the following commits: `d99a407`.

3.2 Trust Issue of Admin Keys

- ID: PVE-002
- Severity: Medium
- Likelihood: Low
- Impact: High
- Target: `FansCreateCore`
- Category: Security Features [3]
- CWE subcategory: CWE-287 [2]

Description

In the `FansCreate` protocol, there is a privileged account (with the `MANAGER_ROLE` assignment) that plays a critical role in governing and regulating the system-wide operations (e.g., assign roles and configure fee parameters). It also has the privilege to control or govern the flow of assets managed by this protocol. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and the related privileged accesses in current contracts.

```
    function setTransferWhitelisted(
        address addr,
        bool whitelisted
    ) external onlyRole(MANAGER_ROLE) {
        transferWhitelisted[addr] = whitelisted;
    }

    function setFeeRatio(
        uint256 _protocolFeeRatio,
        uint256 _projectFeeRatio,
        uint256 _creatorFeeRatio
    ) external onlyRole(MANAGER_ROLE) {
        protocolFeeRatio = _protocolFeeRatio;
        projectFeeRatio = _projectFeeRatio;
        creatorFeeRatio = _creatorFeeRatio;
        emit SetFeeRatio(_protocolFeeRatio, _projectFeeRatio, _creatorFeeRatio);
    }

```

```
    function setProtocolFeeRecipient(
        address _protocolFeeRecipient
    ) external onlyRole(MANAGER_ROLE) {
        protocolFeeRecipient = _protocolFeeRecipient;
        emit SetProtocolFeeRecipient(_protocolFeeRecipient);
    }

    function setProjectFeeRecipient(
        uint256 projectId,
        address _projectFeeRecipient
    ) external onlyRole(MANAGER_ROLE) {
        projectFeeRecipient[projectId] = _projectFeeRecipient;
        emit SetProjectFeeRecipient(projectId, _projectFeeRecipient);
    }

    function setWorkProjectId(
        uint256 workId,
        uint256 projectId
    ) external onlyRole(MANAGER_ROLE) {
        workProjectId[workId] = projectId;
    }
```

Listing 3.2: Example Privileged Operations in `FansCreateCore`

We understand the need of the privileged functions for contract maintenance, but at the same time the extra power to the administrative account may also be a counter-party risk to the protocol users. It would be worrisome if the privileged administrative account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO.

Recommendation Promptly transfer the privileged account to the intended `DAO`-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated as the team makes use of a multi-sig account to hold the privilege.

4 Conclusion

In this audit, we have analyzed the design and implementation of the FansCreate protocol, which is a social component of Xterio with the goal of revolutionizing the way people build their network. Everyone now has the power to invest in the success of their friends through the innovative use of ERC1155 to represent the share ownership. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Moreover, we need to emphasize that Solidity-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
