1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Xterio Launchpool protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several (minor) issues related to either security or performance. This document outlines our audit results.

1.1 About Xterio Launchpool

Xterio Launchpool is an Xterio staking activity where users can stake designated tokens (beginning with XTER) in the Launchpool smart contracts and obtain rewards of tokens from Xterio Ecosystem projects. Each project will configure a redemption time for the staked tokens. When redemption time comes, the staked tokens can be redeemed and the user will receive corresponding rewards based on the staked amount. The specific details of each staking pool are determined by each Xterio Ecosystem project. The basic information of the audited protocol is as follows:

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

		Likelihood	
Impact	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [6]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract

is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `Xterio Launchpool` protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	0	
Low	2	🟦🟦
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 low-severity vulnerabilities.

Table 2.1: Key Xterio LaunchPool Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Accommodation of Non-ERC20-Compliant Tokens	Coding Practices	Resolved
PVE-002	Low	Trust Issue of Admin Keys	Security Features	Mitigated

Besides the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Accommodation of Non-ERC20-Compliant Tokens

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `Launchpool`
- Category: Coding Practices [4]
- CWE subcategory: CWE-1099 [1]

Description

Though there is a standardized ERC-20 specification, many token contracts may not strictly follow the specification or have additional functionalities beyond the specification. In the following, we examine the `transfer()` routine and related idiosyncrasies from current widely-used token contracts.

In particular, we use the popular token, i.e., `ZRX`, as our example. We show the related code snippet below. On its entry of `transfer()`, there is a check, i.e., `if (balances[msg.sender] >= _value && balances[_to] + _value >= balances[_to])`. If the check fails, it returns `false`. However, the transaction still proceeds successfully without being reverted. This is not compliant with the ERC20 standard and may cause issues if not handled properly. Specifically, the ERC20 standard specifies the following: *“Transfers _value amount of tokens to address _to, and MUST fire the Transfer event. The function SHOULD throw if the message caller’s account balance does not have enough tokens to spend.”*

```
    function transfer(address _to, uint _value) returns (bool) {
        //Default assumes totalSupply can't be over max (2^256 - 1).
        if (balances[msg.sender] >= _value && balances[_to] + _value >= balances[_to]) {
            balances[msg.sender] -= _value;
            balances[_to] += _value;
            Transfer(msg.sender, _to, _value);
            return true;
        } else { return false; }
    }

    function transferFrom(address _from, address _to, uint _value) returns (bool) {
        if (balances[_from] >= _value && allowed[_from][msg.sender] >= _value &&
            balances[_to] + _value >= balances[_to]) {
            balances[_to] += _value;
            balances[_from] -= _value;
            allowed[_from][msg.sender] -= _value;
            Transfer(_from, _to, _value);
            return true;
        } else { return false; }
    }
```

Listing 3.1: ZRX::transfer()/transferFrom()

Because of that, a normal call to `transfer()` is suggested to use the safe version, i.e., `safeTransfer()`, In essence, it is a wrapper around ERC20 operations that may either throw on failure or return false without reverts. Moreover, the safe version also supports tokens that return no value (and instead revert or throw on failure). Note that non-reverting calls are assumed to be successful. Similarly, there is a safe version of `approve()/transferFrom()` as well, i.e., `safeApprove()/safeTransferFrom()`.

In the following, we show the `withdraw()` routine in the `Launchpool` contract. If the `USDT` token is provided as `stakeToken`, the unsafe version of `stakeToken.transfer(msg.sender, _amount);` (line 177) may revert as there is no return value in the `USDT` token contract's `transfer()` implementation (but the `IERC20` interface expects a return value)!

```
162     function withdraw(
163         uint256 _amount
164     ) public nonReentrant updateReward(msg.sender) {
165         require(
166             block.timestamp >= withdrawTime,
167             "Launchpool: it's not withdraw time yet"
168         );
169         require(_amount > 0, "Launchpool: can't withdraw 0");
170         require(
171             userStakeAmount[msg.sender] >= _amount,
172             "Launchpool: insufficient balance"
173         );
174 
175         totalStakeAmount -= _amount;
176         userStakeAmount[msg.sender] -= _amount;
177         stakeToken.transfer(msg.sender, _amount);
178 
179         emit XPoolWithdraw(msg.sender, _amount);
180     }
```

Listing 3.2: `Launchpool::withdraw()`

The same issue is also applicable to a number of other routines, including `stake()`, `withdraw()`, `getReward()`, and `withdrawERC20Token()` in the same contract.

Recommendation Accommodate the above-mentioned idiosyncrasy about ERC20-related `approve()/transfer()/transferFrom()`.

Status This issue has been fixed in the following commit: `3df352e`.

3.2 Trust Issue of Admin Keys

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `Launchpool`
- Category: Security Features [3]
- CWE subcategory: CWE-287 [2]

Description

In the `Xterio` protocol, there is a privileged `owner` account that plays a critical role in governing and regulating the system-wide operations (e.g., configure parameters, manage vault, and recover funds). It also has the privilege to control or govern the flow of assets managed by this protocol. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and the related privileged accesses in current contracts.

```
    function updateVaultAddress(address _vaultAddress) external onlyOwner {
        vaultAddress = _vaultAddress;

        emit XPoolUpdateVaultAddress(_vaultAddress);
    }

    function updateGetRewardTime(uint128 _getRewardTime) external onlyOwner {
        getRewardTime = _getRewardTime;

        emit XPoolUpdateGetRewartTime(_getRewardTime);
    }

    function updateWithdrawTime(uint128 _withdrawTime) external onlyOwner {
        require(
            block.timestamp <= startTime,
            "Launchpool: can't exceed start time"
        );

        withdrawTime = _withdrawTime;

        emit XPoolUpdateWithdrawTime(_withdrawTime);
    }

    function updateStakeLimit(
        uint256 _poolStakeLimit,
        uint256 _userStakeLimit
    ) external onlyOwner {
        require(
            block.timestamp <= startTime,
            "Launchpool: can’t exceed start time"
        );

        poolStakeLimit = _poolStakeLimit;
        userStakeLimit = _userStakeLimit;

        emit XPoolUpdateStakeLimit(_poolStakeLimit, _userStakeLimit);
    }

    function withdrawERC20Token(
        address _tokenAddress,
        address _recipient,
        uint256 _tokenAmount
    ) external onlyOwner {
        require(
            _tokenAddress != address(stakeToken),
            "Launchpool: can’t withdraw stake token"
        );

        IERC20(_tokenAddress).transfer(_recipient, _tokenAmount);

        emit XPoolWithdrawERC20Token(_tokenAddress, _recipient, _tokenAmount);
    }
```

Listing 3.3: Example Privileged Operations in `Launchpool`

It is worrisome if the privileged account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Recommendation Promptly transfer the privileged account to the intended `DAO`-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated as the team plans the use of a multi-sig contract for the privileged account.

4 Conclusion

In this audit, we have analyzed the design and implementation of the `Xterio Launchpool` protocol, which is an `Xterio` staking activity where users can stake designated tokens (beginning with `XTER`) in the `Launchpool` smart contracts and obtain rewards of tokens from `Xterio Ecosystem` projects. Each project will configure a redemption time for the staked tokens. When redemption time comes, the staked tokens can be redeemed and the user will receive corresponding rewards based on the staked amount. The specific details of each staking pool are determined by each `Xterio Ecosystem` project. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Moreover, we need to emphasize that `Solidity-based` smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
