## 1 Introduction

Given the opportunity to review the design document and related smart contract source code of the JanisDex protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

#### 1.1 About JanisDex

Arbitrum Janis DEX is a UniswapV2-based decentralized exchange on Arbitrum One. Features include a community fairlaunch release method, multiple token rewards, a transaction fee pool for J tokens, platform dividends received by ownership token holders, extinction pools that sacrifice user deposits in exchange for yield, NFT deposit pools, and NFT yield boosting for farms and pools that reads NFT stats. The basic information of the audited protocol is as follows:

#### 1.2 About PeckShield

PeckShield Inc. [10] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

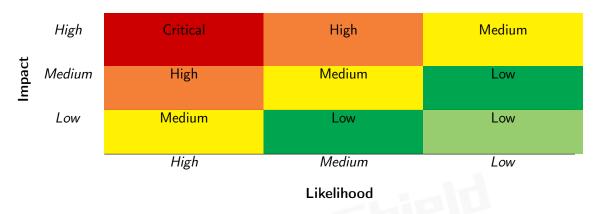

Table 1.2: Vulnerability Severity Classification

### 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [9]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild:
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [8], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values,	a function does not generate the correct return/status code,
Status Codes	or if the application does not handle all possible return/status
	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
	ment of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behav-
	iors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying
	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

# 2 | Findings

#### 2.1 Summary

Here is a summary of our findings after analyzing the JanisDex implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	2
Medium	1
Low	2
Informational	0
Total	5

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 high-severity vulnerabilities, 1 medium-severity vulnerabilities, and 2 low-severity vulnerabilities.

ID **Title** Severity **Status** Category PVE-001 Incorrect K-Invariant Enforcement in Resolved High Business Logic UniswapV2Pair **PVE-002** Implicit Assumption Enforcement In Ad-Resolved Low **Coding Practices** dLiquidity() **PVE-003** Medium Trust Issue of Admin Keys Security Features Mitigated **PVE-004** High Double Minting of Janis Reward in Janis-Business Logic Resolved Minter **PVE-005** Inconsistent Protocol Parameter Enforce-Coding Practices Resolved Low ment in JanisMasterChef

Table 2.1: Key JanisDex Audit Findings

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

## 3 Detailed Results

### 3.1 Incorrect K-Invariant Enforcement in UniswapV2Pair

• ID: PVE-001

• Severity: High

Likelihood: High

• Impact: High

• Target: UniswapV2Pair

• Category: Coding Practices [6]

• CWE subcategory: CWE-1126 [1]

#### Description

The JanisDex protocol is a fork of the popular UniswapV2 protocol with fee adjustment as well as other features. While examining the impact on the enforced K-Invariant due to the fee adjustment, we notice the invariant is not properly enforced.

To elaborate, we show below the related UniswapV2Pair::swap() routine. As the name indicates, this routine performs the actual swap logic with the enforcement of K-Invariant. However, it comes to our attention that the current enforcement (line 223) mis-calculates the precision and may be exploited to drain funds from the pair. The correct enforcement should be the following: require(balance0Adjusted.mul(balance1Adjusted)>= uint(\_reserve0).mul(\_reserve1).mul(10000\*\*2)!

```
199
        function swap(uint amount00ut, uint amount10ut, address to, bytes calldata data)
            external lock {
200
            require(amount0Out > 0 amount1Out > 0, 'UniswapV2: INSUFFICIENT_OUTPUT_AMOUNT')
201
            (uint112 _reserve0, uint112 _reserve1,) = getReserves(); // gas savings
202
            require(amount00ut < _reserve0 && amount10ut < _reserve1, 'UniswapV2:
                INSUFFICIENT_LIQUIDITY');
203
204
            uint balance0;
205
            uint balance1;
206
            { // scope for _token{0,1}, avoids stack too deep errors
207
            address _token0 = token0;
208
            address _token1 = token1;
209
            require(to != _token0 && to != _token1, 'UniswapV2: INVALID_TO');
```

```
210
            if (amount00ut > 0) _safeTransfer(_token0, to, amount00ut); // optimistically
                transfer tokens
211
             if (amount10ut > 0) _safeTransfer(_token1, to, amount10ut); // optimistically
                transfer tokens
212
            if (data.length > 0) IUniswapV2Callee(to).uniswapV2Call(msg.sender, amount00ut,
                amount10ut, data);
213
            balance0 = IERC20Uniswap(_token0).balanceOf(address(this));
214
            balance1 = IERC20Uniswap(_token1).balanceOf(address(this));
215
            uint amount0In = balance0 > _reserve0 - amount0Out ? balance0 - (_reserve0 -
216
                amount00ut) : 0;
217
            uint amount1In = balance1 > _reserve1 - amount1Out ? balance1 - (_reserve1 -
                amount1Out) : 0;
218
            require(amount0In > 0 amount1In > 0, 'UniswapV2: INSUFFICIENT_INPUT_AMOUNT');
219
            { // scope for reserve{0,1}Adjusted, avoids stack too deep errors
220
            uint _swapFee = swapFee;
221
            uint balanceOAdjusted = (balanceO.mul(10000).sub(amountOIn.mul(_swapFee)));
222
            uint balance1Adjusted = (balance1.mul(10000).sub(amount1In.mul(_swapFee)));
223
            require(balance0Adjusted.mul(balance1Adjusted) >= uint(_reserve0).mul(_reserve1)
                .mul(1000**2), 'UniswapV2: K');
224
225
226
            _update(balance0, balance1, _reserve0, _reserve1);
227
            emit Swap(msg.sender, amount0In, amount1In, amount0Out, amount1Out, to);
228
```

Listing 3.1: UniswapV2Pair::swap()

**Recommendation** Revise the above logic to properly enforce the K-Invariant. Note that the same issue is also present in the library UniswapV2Library.

**Status** The issue has been fixed by following our suggestion.

## 3.2 Implicit Assumption Enforcement In AddLiquidity()

• ID: PVE-002

• Severity: Low

Likelihood: Low

• Impact: Low

• Target: UniswapV2Router02

Category: Coding Practices [6]

• CWE subcategory: CWE-628 [3]

#### Description

In the UniswapV2Router02 contract, the addLiquidity() routine (see the code snippet below) is provided to add amountADesired amount of tokenA and amountBDesired amount of tokenB into the pool as liquidity via the UniswapRouterV2::addLiquidity() routine. To elaborate, we show below the related code snippet.

```
function _addLiquidity(
            address tokenA,
35
36
            address tokenB,
37
            uint amountADesired,
38
            uint amountBDesired,
39
            uint amountAMin,
40
            uint amountBMin
41
        ) internal virtual returns (uint amountA, uint amountB) {
42
            // create the pair if it doesn't exist yet
43
            if (IUniswapV2Factory(factory).getPair(tokenA, tokenB) == address(0)) {
44
                IUniswapV2Factory(factory).createPair(tokenA, tokenB);
45
46
            (uint reserveA, uint reserveB) = UniswapV2Library.getReserves(factory, tokenA,
                tokenB);
47
            if (reserveA == 0 && reserveB == 0) {
48
                (amountA, amountB) = (amountADesired, amountBDesired);
49
            } else {
50
                uint amountBOptimal = UniswapV2Library.quote(amountADesired, reserveA,
                    reserveB);
51
                if (amountBOptimal <= amountBDesired) {</pre>
52
                    require(amountBOptimal >= amountBMin, 'UniswapV2Router:
                        INSUFFICIENT_B_AMOUNT');
53
                    (amountA, amountB) = (amountADesired, amountBOptimal);
54
                } else {
55
                    uint amountAOptimal = UniswapV2Library.quote(amountBDesired, reserveB,
                        reserveA);
56
                    assert(amountAOptimal <= amountADesired);</pre>
57
                    require(amountAOptimal >= amountAMin, 'UniswapV2Router:
                        INSUFFICIENT_A_AMOUNT');
58
                    (amountA, amountB) = (amountAOptimal, amountBDesired);
59
                }
60
            }
61
62
        function addLiquidity(
63
            address tokenA,
64
            address tokenB,
65
            uint amountADesired,
66
            uint amountBDesired,
67
            uint amountAMin,
68
            uint amountBMin,
69
            address to,
70
            uint deadline
71
        ) external virtual override ensure(deadline) returns (uint amountA, uint amountB,
            uint liquidity) {
72
            (amountA, amountB) = _addLiquidity(tokenA, tokenB, amountADesired,
                amountBDesired, amountAMin, amountBMin);
73
            address pair = UniswapV2Library.pairFor(factory, tokenA, tokenB);
74
            TransferHelper.safeTransferFrom(tokenA, msg.sender, pair, amountA);
75
            TransferHelper.safeTransferFrom(tokenB, msg.sender, pair, amountB);
76
            liquidity = IUniswapV2Pair(pair).mint(to);
77
```

Listing 3.2: UniswapV2Router02::addLiquidity()

It comes to our attention that the Uniswap V2 Router has implicit assumptions on the \_addLiquidity () routine. The above routine takes two amounts: amountXDesired and amountXMin. The first amount amountXDesired determines the desired amount for adding liquidity to the pool and the second amount amountXMin determines the minimum amount of used assets. There are two implicit conditions, i.e., amountADesired >= amountAMin and amountBDesired >= amountBMin. However, if these two conditions are not met, current logic will not trigger reverts because the code above performs asymmetric checks for these amounts. Hence, without stating these assumptions, slippage control for some trades on Uniswap V2 Router may not be checked and may not be taken into account at all in certain scenarios.

Recommendation Make the requirement of amountADesired >= amountAMin and amountBDesired >= amountBMin explicitly in the addLiquidity() function.

**Status** The issue has been fixed by adding the suggested requirement.

### 3.3 Trust Issue of Admin Keys

• ID: PVE-003

Severity: MediumLikelihood: Medium

• Impact: Medium

• Target: Multiple Contracts

• Category: Security Features [5]

• CWE subcategory: CWE-287 [2]

### Description

In the JanisDex protocol, there is a privileged owner account that plays a critical role in governing and regulating the system-wide operations (e.g., configure protocol parameters and add/adjust new reward pools). In the following, we use the JanisMasterChef contract as an example and show the representative functions potentially affected by the privileges of the owner.

```
784
         function updateJanisEmissionRate(uint _JanisPerSecond) public onlyOwner {
785
             require(_JanisPerSecond < 1e22, "emissions too high!");</pre>
786
             massUpdatePools();
             JanisPerSecond = _JanisPerSecond;
787
788
             emit UpdateJanisEmissionRate(msg.sender, _JanisPerSecond);
789
        }
790
791
         function updateYieldTokenEmissionRate(uint _yieldTokenPerSecond) public onlyOwner {
792
             require(_yieldTokenPerSecond < 1e22, "emissions too high!");</pre>
793
             massUpdatePools();
794
             yieldTokenPerSecond = _yieldTokenPerSecond;
795
             emit UpdateYieldTokenEmissionRate(msg.sender, _yieldTokenPerSecond);
```

796

Listing 3.3: Example Privileged Operations in the JanisMasterChef Contract

We understand the need of the privileged functions for contract maintenance, but at the same time the extra power to the privileged account may also be a counter-party risk to the protocol users. It is worrisome if the privileged account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO.

Recommendation Promptly transfer the privileged accounts to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

This issue has been confirmed and the team plans to use a multi-sig to manage the admin account.

#### 3.4 Double Minting of Janis Reward in JanisMinter

• ID: PVE-004

• Severity: High • Likelihood: High

• Impact: High

• Target: JanisMinter

Category: Business Logic [7]

CWE subcategory: CWE-837 [4]

#### Description

To facilitate the token issuance and management, the JanisDex protocol has a JanisMinter contract, which is the sole entity to have the privilege to mint new JanisToken. While reviewing various scenarios for token issuance, we notice a specific routine has a flawed implementation.

To elaborate, we show below the related mintReferralsOnly() function. It implements a rather straightforward logic in minting the commission to the referrer as well as the reward to the referee, i.e., the user. It comes to our attention the user reward is incorrectly minted as it mints the \_minting amount (line 135) one more time!

```
119
        function mintReferralsOnly(address _user, uint _minting) public onlyOperator {
120
             uint commission = _minting * referralBonusE4 / 1e4;
121
             uint reward = _minting * refereeBonusE4 / 1e4;
122
123
             address referrer = referrers[_user];
124
125
             if (referrer != address(0) && _user != address(0) && commission > 0) {
```

```
126
                 totalReferralCommission[referrer] += commission;
127
                 totalReferralCommissionPerUser[referrer][_user] += commission;
128
129
                 JanisToken.mint(referrer, commission);
130
131
                 emit JanisMinted(referrer, commission);
132
                 emit ReferralCommissionRecorded(referrer, _user, commission);
133
             }
134
             if (_user != address(0) && referrer != address(0) && reward > 0) {
135
                 JanisToken.mint(_user, _minting);
136
                 totalRefereeReward[_user] += reward;
137
                 totalRefereeRewardPerReferrer[_user][referrer] += reward;
138
139
                 JanisToken.mint(_user, reward);
140
141
                 emit JanisMinted(_user, reward);
142
                 emit ReferralCommissionRecorded(_user, referrer, reward);
143
             }
144
```

Listing 3.4: JanisMinter::mintReferralsOnly()

**Recommendation** Revise the above routine to ensure only commission and reward are minted.

**Status** The issue has been fixed with the suggestion implemented.

## 3.5 Inconsistent Protocol Parameter Enforcement in JanisMasterChef

• ID: PVE-005

• Severity: Low

Likelihood: Low

• Impact: Low

• Target: JanisMasterChef

• Category: Coding Practices [6]

• CWE subcategory: CWE-1126 [1]

#### Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The JanisDEX protocol is no exception. Specifically, if we examine the JanisMasterChef contract, it has defined a number of protocol-wide risk parameters, such as depositFeeBPOrNFTETHFee and JanisPerSecond. In the following, we show the corresponding routines that allow for their changes.

```
function setDepositFeeOnly(uint _pid, uint _depositFeeBPOrNFTETHFee, bool
    _withMassUpdate) public onlyOwner {
    if (_withMassUpdate) {
        massUpdatePools();
    }
}
```

```
347
             } else {
348
                  updatePool(_pid);
349
350
351
             poolInfo[ pid].depositFeeBPOrNFTETHFee;
352
         }
353
         function setPoolScheduleKeepMultipliers(uint pid, uint startTime, uint endTime,
354
             bool withMassUpdate) external onlyOwner {
355
             require(_startTime == 0 _startTime > block.timestamp, "invalid startTime!");
             require(_endTime == 0 (_startTime == 0 && _endTime > block.timestamp + 20) (
356
                  startTime > block.timestamp && endTime > startTime + 20), "invalid
                  endTime!");
357
358
             if ( withMassUpdate) {
359
                  massUpdatePools();
360
             } else {
361
                  updatePool( pid);
362
363
             uint lastRewardTime = _startTime == 0 ? (block.timestamp > globalStartTime ?
364
                  \color{red} \textbf{block.timestamp} \; : \; \; \texttt{globalStartTime}) \; : \; \; \underline{\hspace{1cm}} \texttt{startTime};
365
366
             poolInfo[ pid].lastRewardTime = lastRewardTime;
367
             poolInfo[_pid].endTime = _endTime;
368
```

Listing 3.5: JanisMasterChef::setDepositFeeOnly()/setPoolScheduleKeepMultipliers()

These parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. Based on the current implementation, certain corner cases may lead to an undesirable consequence. For example, the depositFeeBPOrNFTETHFee parameter has the expection of require(\_depositFeeBPOrNFTETHFee <= 10000, "too high fee"), which is not enforced in the above setDepositFeeOnly().

**Recommendation** Consistently validate any changes regarding these system-wide parameters to ensure they fall in an appropriate range.

**Status** The issue has been fixed by implementing the above suggestion.

## 4 Conclusion

In this audit, we have analyzed the JanisDex protocol design and implementation. It is a UniswapV2 -based decentralized exchange on Arbitrum One. Features include a community fairlaunch release method, multiple token rewards, a transaction fee pool for J tokens, platform dividends received by ownership token holders, extinction pools that sacrifice user deposits in exchange for yield, NFT deposit pools, and NFT yield boosting for farms and pools that reads NFT stats. During the audit, we notice that the current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
