## 1 Introduction

Given the opportunity to review the design document and related smart contract source code of the <code>BridgeAssist</code> smart contract, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

### 1.1 About BridgeAssist

BridgeAssist is a bridge smart contract and it has the actions of Collect and Dispense. User can make use of it to transfer the Crypto4All supported tokens between different blockchains with the help of the backend endpoint. The unique design of the Tozex bridge allows users to swap their Tozex marketplace assets using a multi-signature scheme on all eligible blockchain networks.

The basic information of the audited protocol is as follows:

Item Description
Target BridgeAssist
Website https://crypto4all.com/
Type Solidity Smart Contract
Platform Solidity
Audit Method Whitebox
Latest Audit Report May 10, 2023

Table 1.1: Basic Information of BridgeAssist

In the following, we show the Git repository of reviewed files and the commit hash value used in this audit. Note this protocol assumes a trusted external oracle, which is not part of the audit.

https://github.com/Tozex/TokenMultisigBridge/blob/master/contracts/BridgeAssist.sol (1be52d5)

And this is the Git repository and commit ID after all fixes for the issues found in the audit have been checked in:

• <a href="https://github.com/Tozex/TokenMultisigBridge/blob/master/contracts/BridgeAssist.sol">https://github.com/Tozex/TokenMultisigBridge/blob/master/contracts/BridgeAssist.sol</a> (ec8838d)

#### 1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

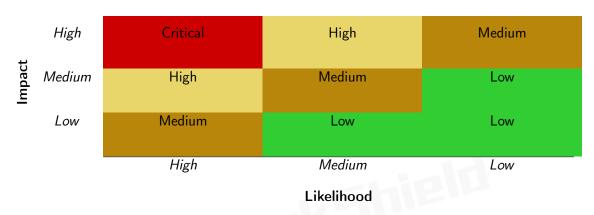

Table 1.2: Vulnerability Severity Classification

### 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [6]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

Table 1.3: The Full List of Check Items

Category	Check Item		
	Constructor Mismatch		
	Ownership Takeover		
	Redundant Fallback Function		
	Overflows & Underflows		
	Reentrancy		
	Money-Giving Bug		
	Blackhole		
	Unauthorized Self-Destruct		
Basic Coding Bugs	Revert DoS		
Dasic Coung Dugs	Unchecked External Call		
	Gasless Send		
	Send Instead Of Transfer		
	Costly Loop		
	(Unsafe) Use Of Untrusted Libraries		
	(Unsafe) Use Of Predictable Variables		
	Transaction Ordering Dependence		
	Deprecated Uses		
Semantic Consistency Checks	Semantic Consistency Checks		
	Business Logics Review		
	Functionality Checks		
	Authentication Management		
	Access Control & Authorization		
	Oracle Security		
Advanced DeFi Scrutiny	Digital Asset Escrow		
Advanced Berr Scrating	Kill-Switch Mechanism		
	Operation Trails & Event Generation		
	ERC20 Idiosyncrasies Handling		
	Frontend-Contract Integration		
	Deployment Consistency		
	Holistic Risk Management		
	Avoiding Use of Variadic Byte Array		
	Using Fixed Compiler Version		
Additional Recommendations	Making Visibility Level Explicit		
	Making Type Inference Explicit		
	Adhering To Function Declaration Strictly		
	Following Other Best Practices		

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary		
Configuration	Weaknesses in this category are typically introduced during		
	the configuration of the software.		
Data Processing Issues	Weaknesses in this category are typically found in functional-		
	ity that processes data.		
Numeric Errors	Weaknesses in this category are related to improper calcula-		
	tion or conversion of numbers.		
Security Features	Weaknesses in this category are concerned with topics like		
	authentication, access control, confidentiality, cryptography,		
	and privilege management. (Software security is not security		
	software.)		
Time and State	Weaknesses in this category are related to the improper man-		
	agement of time and state in an environment that supports		
	simultaneous or near-simultaneous computation by multiple		
Forman Canadiai ana	systems, processes, or threads.		
Error Conditions,	Weaknesses in this category include weaknesses that occur if		
Return Values, Status Codes	a function does not generate the correct return/status code, or if the application does not handle all possible return/status		
Status Codes	codes that could be generated by a function.		
Resource Management	Weaknesses in this category are related to improper manage-		
Resource Management	ment of system resources.		
Behavioral Issues	Weaknesses in this category are related to unexpected behav-		
Deliavioral issues	iors from code that an application uses.		
Business Logics	Weaknesses in this category identify some of the underlying		
Dusiness Togics	problems that commonly allow attackers to manipulate the		
	business logic of an application. Errors in business logic can		
	be devastating to an entire application.		
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used		
	for initialization and breakdown.		
Arguments and Parameters	Weaknesses in this category are related to improper use of		
	arguments or parameters within function calls.		
Expression Issues	Weaknesses in this category are related to incorrectly written		
	expressions within code.		
Coding Practices	Weaknesses in this category are related to coding practices		
	that are deemed unsafe and increase the chances that an ex-		
	ploitable vulnerability will be present in the application. They		
	may not directly introduce a vulnerability, but indicate the		
	product has not been carefully developed or maintained.		

# 2 | Findings

### 2.1 Summary

Here is a summary of our findings after analyzing the BridgeAssist protocol implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	0	
Low	2	
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 2 low-severity vulnerabilities.

Table 2.1: Key BridgeAssist Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Accommodation of Non-ERC20-	Business Logic	Resolved
		Compliant Tokens		
PVE-002	Low	Trust Issue of Admin Keys	Security Features	Mitigated

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

# 3 Detailed Results

### 3.1 Accommodation of Non-ERC20-Compliant Tokens

• ID: PVE-001

Severity: Low

Likelihood: Low

Impact: Medium

• Target: BridgeAssist

• Category: Business Logic [4]

CWE subcategory: CWE-841 [2]

#### Description

Though there is a standardized ERC-20 specification, many token contracts may not strictly follow the specification or have additional functionalities beyond the specification. In the following, we examine the transfer() routine and related idiosyncrasies from current widely-used token contracts.

In particular, we use the popular token, i.e., ZRX, as our example. We show the related code snippet below. On its entry of transfer(), there is a check, i.e., if (balances[msg.sender] >= \_value && balances[\_to] + \_value >= balances[\_to]). If the check fails, it returns false. However, the transaction still proceeds successfully without being reverted. This is not compliant with the ERC20 standard and may cause issues if not handled properly. Specifically, the ERC20 standard specifies the following: "Transfers \_ value amount of tokens to address \_ to, and MUST fire the Transfer event. The function SHOULD throw if the message caller's account balance does not have enough tokens to spend."

```
function transfer(address _to, uint _value) returns (bool) {
64
65
            //Default assumes total
Supply can't be over max (2^256 - 1).
66
            if (balances[msg.sender] >= value && balances[ to] + value >= balances[ to]) {
67
                balances [msg.sender] -= _value;
                balances[_to] += _value;
68
69
                Transfer (msg. sender, to, value);
70
                return true;
71
           } else { return false; }
72
       }
74
       function transferFrom(address _from, address _to, uint _value) returns (bool) {
```

```
75
            if (balances [ from ] >= value && allowed [ from ] [msg.sender ] >= value &&
                balances [ to] + value >= balances [ to]) {
76
                balances [_to] += _value;
                balances [ from ] — value;
77
78
                allowed [ from ] [msg.sender] -= value;
79
                Transfer (_from, _to, _value);
80
                return true;
81
            } else { return false; }
82
```

Listing 3.1: ZRX::transfer()/transferFrom()

Because of that, a normal call to transfer() is suggested to use the safe version, i.e., safeTransfer (), In essence, it is a wrapper around ERC20 operations that may either throw on failure or return false without reverts. Moreover, the safe version also supports tokens that return no value (and instead revert or throw on failure). Note that non-reverting calls are assumed to be successful. Similarly, there is a safe version of transferFrom() as well, i.e., safeTransferFrom().

In the following, we show the executeTransaction() routine. If the USDT token is supported as token, the unsafe version of IERC20(token).transferFrom(txn.destination, address(this), txn.value); (line 154 and 157) may revert as there is no return value in the USDT token contract's transfer() /transferFrom() implementation (but the IERC20 interface expects a return value)!

```
148
        function executeTransaction(uint transactionId) internal notExecuted(transactionId)
             returns (bool) {
149
             if (isConfirmed(transactionId)) {
150
                 Transaction storage txn = transactions[transactionId];
151
                 address token = tokens[txn.tokenIndex];
152
                 txn.executed = true;
                 if(txn.code == COLLECT_CODE) {
153
                     IERC20(token).transferFrom(txn.destination, address(this), txn.value);
154
155
                     emit Collect(txn.destination, txn.value);
156
                 } else {
157
                     IERC20(token).transfer(txn.destination, txn.value);
158
                     emit Dispense(txn.destination, txn.value);
159
                 }
160
                 return true;
161
            }
162
             return false;
163
```

Listing 3.2: BridgeAssist::executeTransaction()

**Recommendation** Accommodate the above-mentioned idiosyncrasy about ERC20-related transfer()/transferFrom().

Status The issue has been fixed by this commit: ec8838d.

### 3.2 Trust Issue of Admin Keys

• ID: PVE-002

Severity: Low

Likelihood: Low

• Impact: Low

• Target: BridgeAssist

• Category: Security Features [3]

CWE subcategory: CWE-287 [1]

#### Description

In the BridgeAssist smart contract, there is a privileged owner account that plays a critical role in governing and regulating the protocol-wide operations (e.g., configure various system parameters and assign other roles, pause the contract). Also there is a privileged relayer account that can submit the transaction. In the following, we show the representative functions potentially affected by the privilege of the account.

```
83
         function pause() external onlyOwner {
 84
             _pause();
 85
 86
 87
         function unpause() external onlyOwner {
 88
             _unpause();
 89
        }
 90
 91
         function addToken(address token) external onlyOwner notNull(token) {
 92
             tokens[lastTokenIndex++] = token;
 93
             emit AddToken(msg.sender, token);
 94
 95
 96
         function setDev(address _dev) external onlyOwner notNull(_dev) {
 97
             dev = _dev;
 98
             emit SetDev(msg.sender, _dev);
99
100
101
         function setRelayer(address _relayer) external onlyOwner notNull(_relayer) {
102
             relayer = _relayer;
103
             emit SetRelayer(msg.sender, _relayer);
104
        }
105
106
         function submitTransaction(address payable destination, uint tokenIndex, uint value,
             uint code) external nonReentrant whenNotPaused returns (uint transactionId) {
107
             require(msg.sender == relayer, "only hotwallet can call this function");
108
             uint txTimestamp = _getNow();
109
             transactionId = addTransaction(destination, tokenIndex, value, code, txTimestamp
                 );
110
             if(code == COLLECT_CODE) {
111
                 confirmations[transactionId][destination] = true;
112
                 executeTransaction(transactionId);
```

```
113 }
114 }
```

Listing 3.3: Example Privileged Operations in BridgeAssist

We emphasize that the privilege assignment may be necessary and consistent with the protocol design. However, it would be worrisome if the privileged account is not governed by a DAO-like structure. Note that a compromised account would allow the attacker to modify a number of sensitive system parameters, which directly undermines the assumption of the protocol design.

**Recommendation** Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status The team has confirmed multi-sig will be used for the privileged accounts.

# 4 Conclusion

In this audit, we have analyzed the design and implementation of the BridgeAssist protocol. The current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
