1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Asteriod X launchpad, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Asteriod X

Asteriod X is an innovative mining investment platform that connects mining companies with global investors through blockchain technology. All NFTs on the platform adhere to the ERC-1155 standard, ensuring versatility and efficient transactions. Asteroid X offers a transparent trading mechanism and high-quality investment opportunities, creating a win-win scenario for mining companies and crypto investors alike. The basic information of audited contracts is as follows:

Item Description
Target Asteriod X
Type EVM Smart Contract
Language Solidity
Audit Method Whitebox

1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

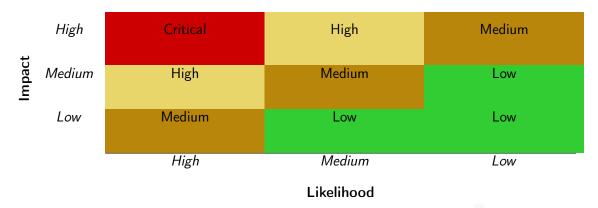

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [8]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further

deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values,	a function does not generate the correct return/status code,
Status Codes	or if the application does not handle all possible return/status
	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
	ment of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behav-
	iors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying
	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the Asteriod X launchpad. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	0
Medium	1
Low	2
Informational	0
Total	3

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 2 low-severity vulnerabilities.

Status ID Title Severity Category PVE-001 Low Improved Validation of Function Pa-Coding Practices Resolved **PVE-002** Low Improved Precision By Multiplication Numeric Errors And Division Reordering PVE-003 Medium Trust Issue Of Admin Keys Security Features Mitigated

Table 2.1: Key Asteriod X Audit Findings

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Improved Validation of Function Parameters

• ID: PVE-001

Severity: LowLikelihood: Low

• Impact: Low

• Target: ERC1155Asteroid

• Category: Coding Practices [5]

• CWE subcategory: CWE-1126 [1]

Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The audited launchpad contract is no exception. Specifically, if we examine the ERC1155Asteroid contract, it has defined a number of NFT-specific risk parameters, such as tokenMinAmounts and tokenMaxAmounts. In the following, we show the corresponding routine that initializes their values.

```
227
         function validateParameters(
228
             uint256 _id,
229
             uint256 _initialSupply,
230
             uint256 _initialRaisedAmounts,
231
             uint256 _initialMinAmount,
232
             uint256 _initialMaxAmount,
             address _initialFundsWallet
233
234
         ) internal view {
235
             require(!_exists(_id), "token _id already exists");
236
             require(
237
                 _initialFundsWallet != address(0),
238
                 "Invalid initialFunds Wallet"
239
             );
240
             require(
241
                 _initialSupply > 0 &&
242
                     \_initialRaisedAmounts > 0 \&\&
243
                     _initialMinAmount > 0 &&
244
                     _initialMaxAmount > 0,
245
                 "Invalid amount"
```

```
246
247
             require(
                 _initialRaisedAmounts >= _initialSupply,
248
249
                 "Invalid funds and shares raised"
250
             );
251
             uint256 perShares = perShareValue(
252
                 _initialRaisedAmounts,
253
                 _initialSupply
254
             );
255
             require(_initialMinAmount >= perShares, "Invalid shares");
256
```

Listing 3.1: ERC1155Asteroid::validateParameters()

These parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on these parameters can be improved by applying more rigorous sanity checks. Based on the current implementation, certain corner cases may lead to an undesirable consequence. For example, the above routine can be improved by enforcing the following requirement, i.e., require(_initialMaxAmount >= _initialMinAmount) (line 244).

Recommendation Validate any changes regarding these system-wide parameters to ensure they fall in an appropriate range.

Status The issue has been resolved by following the above suggestion.

3.2 Improved Precision By Multiplication And Division Reordering

• ID: PVE-002

• Severity: Low

• Likelihood: Medium

• Impact: Low

• Target: ERC1155Asteroid

Category: Numeric Errors [6]

• CWE subcategory: CWE-190 [2]

Description

SafeMath is a widely-used Solidity math library that is designed to support safe math operations by preventing common overflow or underflow issues when working with uint256 operands. While it indeed blocks common overflow or underflow issues, the lack of float support in Solidity may introduce another subtle, but troublesome issue: precision loss. In this section, we examine one possible precision loss source that stems from the different orders when both multiplication (mul) and division (div) are involved.

In particular, we use the ERC1155Asteroid::calculQuantities() as an example. This routine is used to calculate the resulting quantity of a particular purchase.

```
function calculQuantities(uint256 id, uint256 amount)
308
309
             internal
310
             view
311
             returns (uint256)
312
313
             uint256 totalAmounts = tokenRaisedAmounts[id];
314
             uint256 supply = tokenSupply[id];
315
             (, uint256 perSV) = Math.tryDiv(totalAmounts, supply);
316
             (, uint256 quantity) = Math.tryDiv(amount, perSV);
317
             return quantity;
318
```

Listing 3.2: ERC1155Asteroid::calculQuantities()

We notice the calculation of the resulting quantity (line 317) involves mixed multiplication and devision. For improved precision, it is better to calculate the multiplication before the division, i.e., amount * totalAmounts / supply . Note that the resulting precision loss may be just a small number, but it plays a critical role when certain boundary conditions are met. And it is always the preferred choice if we can avoid the precision loss as much as possible.

Recommendation Revise the above calculations to better mitigate possible precision loss.

Status The issue has been resolved by following the above suggestion.

3.3 Trust Issue Of Admin Keys

• ID: PVE-003

Severity: Medium

• Likelihood: Medium

Impact: Medium

• Target: Multiple Contracts

Category: Security Features [4]

• CWE subcategory: CWE-287 [3]

Description

The audited launchpad contract has a privileged account (either owner or the account with the DEFAULT_ADMIN_ROLE role) that plays a critical role in governing and regulating the protocol-wide operations (e.g., configure parameters, assign other roles, and recover stuck funds). In the following, we show the representative functions potentially affected by the privilege of this account.

```
function setPaymentCoin(IERC20Metadata _iERC20Metadata) external onlyOwner {

require(

paymentCoin != _iERC20Metadata,

"LaunchPadAsteroid#setERC1155AsteroidContract: PaymentCoin has been already

configured"
```

```
100
101
             paymentCoin = _iERC20Metadata;
102
103
104
105
         * @dev set to asteroid contract
106
         */
107
         function setERC1155AsteroidContract(IERC1155Asteroid _iERC1155Asteroid)
108
             external
109
             onlyOwner
110
         {
111
             require(
112
                 iERC1155Asteroid != _iERC1155Asteroid,
113
                 "LaunchPadAsteroid#setERC1155AsteroidContract: ERC1155Asteroid has been
                     already configured"
114
             );
115
             iERC1155Asteroid = _iERC1155Asteroid;
116
         }
117
118
         function pause() external onlyOwner {
             _pause();
119
120
121
         function unpause() external onlyOwner {
122
123
             _unpause();
124
125
126
127
         * @dev If this contract has other funds, emergency withdrawal
128
129
         function withdraw(
130
             address to,
131
             address erc20Address,
132
             uint256 amount
133
         ) external onlyOwner {
134
             uint256 balance = IERC20Metadata(erc20Address).balanceOf(address(this));
135
             require(balance >= amount, "Insufficient balance!");
136
             IERC20Metadata(erc20Address).safeTransfer(to, amount);
137
```

Listing 3.3: Example Privileged Operations in LaunchPadAsteroid

We emphasize that the privilege assignment may be necessary and consistent with the protocol design. However, it is worrisome if the privileged account is not governed by a DAO-like structure. Note that a compromised account would allow the attacker to modify a number of sensitive vault parameters, which directly undermines the assumption of the vault design.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the in-

tended trustless nature and high-quality distributed governance.

Status The issue has been confirmed and will be mitigated with the use of a multi-sig to manage the privileged account.

4 Conclusion

In this audit, we have analyzed the design and implementation of the launchpad in Asteriod X, which is an innovative mining investment platform that connects mining companies with global investors through blockchain technology. All NFTs on the platform adhere to the ERC-1155 standard, ensuring versatility and efficient transactions. Asteroid X offers a transparent trading mechanism and high-quality investment opportunities, creating a win-win scenario for mining companies and crypto investors alike. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
